From Formal Authority to Practical Human Control

A traceable method for reconstructing human control in automated decisions

Preprint candidate v0.14.0 | Not peer reviewed

Abstract

Institutions often treat a named reviewer or approval step as evidence that an automated system remains under human control. That inference can fail when the person lacks timely information, comprehension, authority, an opportunity to challenge the system, or the ability to affect the outcome. This paper develops a frozen, evidence-traceable procedure for representing formal authority, practical control, and unresolved evidence in bounded public incident records. Before case screening, the protocol fixed the evidence cutoff, candidate collections, eligibility rules, screening order, selection strata, and missing-data treatment. Three versioned historical case packets record claim-level provenance, categorical evidence states, and a chain from information access through effect. A frozen reanalysis changed six Oko pre-action stages from supported to partially supported. The current assessments record partial support across those Oko stages, supported authority with unsupported practical conditions in Patriot ZG710, and supported authority with unresolved conditions in the Patriot F/A-18C case. An open-index search produced 2,431 deduplicated records. Author screening and forward-citation review yielded five bounded source propositions for manuscript use, two background-only sources, and six quarantined sources. The contribution is a governance-specific integration with a visible correction path. Institutions claiming human control bear an ethical burden to preserve evidence of practical force because unsupported attribution can obscure responsibility and exposure to harm. Three retrospective, single-assessor cases supply no population estimate, causal validation, independent-reliability result, or transfer claim for current learned systems. **Keywords:** human oversight; meaningful human control; AI governance; incident reconstruction; assurance

Resolved evidence decision

`PAPER-BLOCKER-01` identified a mismatch between Oko's released v0.3 supported states and the protocol's direct-and-contemporaneous evidence rule. The v0.6 adjudication protocol was frozen before reassessment. The resulting change ledger records six transitions to partially supported and preserves v0.3.0 as release history. Missing contemporaneous records remain a limitation.

1. Introduction

1.1 The institutional problem

An approval step proves that an institution assigned a role. It does not show that the person received the relevant information, understood the system's limits, could challenge the proposed action in time, exercised that authority, or changed the outcome. A human-control claim therefore contains several empirical propositions that a signature or job title cannot establish by itself. Human-factors research explains the mechanism. Automation can leave people responsible for rare or abnormal conditions after routine system operation has reduced their preparation for those conditions (Bainbridge, 1983). Situation awareness and intervention performance depend on what the person can perceive, understand, and project under the operating conditions (Endsley, 2017). Trust affects reliance through the interaction of

the person, system, task, and context (Lee & See, 2004). Formal authority can remain intact as these operational conditions deteriorate. The same problem appears in policy. Green finds that government rules often require human oversight without establishing that the designated people can perform the intended review (Green, 2022). Zhu et al. separate AI operative agency from human evaluative agency and identify verification, contestation, and substitution as oversight mechanisms (Zhu et al., 2026). These accounts direct attention to a documentary question: what evidence would justify reliance on an institutional claim that human authority had practical force in one consequential decision?

1.2 Research gap

Five research streams answer parts of that question. Meaningful-human-control scholarship defines moral, design, and institutional conditions for control (Santoni de Sio & van den Hoven, 2018; Siebert et al., 2023; Davidovic, 2023; Calvert, 2025). Human-factors research explains why monitoring, comprehension, and timely intervention can fail (Bainbridge, 1983; Lee & See, 2004; Endsley, 2017). Oversight research identifies causal power, epistemic access, preparedness, intention, human learning, and institutional design as conditions for effectiveness (Sterz et al., 2024; Te'eni et al., 2025; Laux, 2024; Baum & Laux, 2026). Incident research specifies causal factors, reporting structures, and information needs (McGregor, 2021; Macrae, 2022; Ezell et al., 2025; Paeth et al., 2025; Wei & Heim, 2026). Assurance and traceability research connects claims to evidence, assumptions, uncertainty, validation rules, and provenance (Burr & Leslie, 2023; Paterson et al., 2025; Meng et al., 2026; Moghaddam, 2026). The closest prior work sharply limits the present claim. Sterz et al. define effective oversight through sufficient causal power, suitable epistemic access, self-control, and fitting intentions (Sterz et al., 2024). Verdiesen, Santoni de Sio, and Dignum place oversight across technical, sociotechnical, and governance layers (Verdiesen et al., 2021). Laux treats overseer competence and incentives as institutional-design problems (Laux, 2024). Almada connects human intervention to the information and system conditions needed for contestability (Almada, 2019). Douer and Meyer show that causal responsibility can diverge from assigned human functions (Douer & Meyer, 2020). Prior methods also cover reconstruction and evidence. Dekker reconstructs human contributions inside an event sequence while controlling hindsight (Dekker, 2002). Pittaras and McGregor classify possible failure causes from incomplete open-source AI incidents (Pittaras & McGregor, 2023). ScientistOne supplies claim-level evidence chains and post-hoc integrity checks (Meng et al., 2026). Moghaddam proposes evidence-linked formal argument graphs with deterministic validation and provenance (Moghaddam, 2026). Alhalangy joins selective human review to a structured case-level audit trail in a synthetic institutional study (Alhalangy, 2026). Recent close sources go further: Bahidika applies oversight tiers to public AI Incident Database records (Bahidika, 2026), LaPosta publishes a runnable decision-chain protocol (LaPosta, 2026), Niazi, Hassani, and Lee define a versioned assurance case with a practical-override trace (Niazi et al., 2026), and Surve, Shabtai, and Elovici declare an audit-evidence method with a retrospective Cruise application (Surve et al., 2026). The remaining contribution is one governance-specific integration: protocol fixation before case screening, a visible selection and stopping path, versioned public evidence packets, categorical missingness, a chain from information access through effect, claim-specific evidence fitness, conclusion dependency closure, versioned correction, and executable artifact checks. The formal search records 2,431 deduplicated records and preserves the limits created by inaccessible abstracts, one unresolved citation seed, and unavailable authenticated databases. The paper therefore states a bounded integration claim. Universal originality remains outside the evidence.

1.3 Research question and contribution

> *How can a frozen, evidence-traceable assessment procedure represent formal human authority, practical human control, and unresolved evidence in a bounded public incident record?*

The paper proposes a documentary assessment procedure. It defines a bounded action sequence, fixes the case-selection and missing-data rules, assembles a versioned evidence packet, assigns provenance to material statements, and evaluates six pre-action conditions: access, comprehension, authority, feasible challenge, exercised challenge, and effect. An explicit indeterminate state prevents missing records from becoming negative factual findings. A correction ledger preserves earlier outputs when a later adjudication changes a state. The three cases demonstrate that procedure under contrastive evidence conditions. They do not test prevalence, classification accuracy, independent reliability, causal effects, or transfer to current learned systems. The institutional output is a proposed record set that a reviewer would need before relying on a practical-control claim. The ethical proposition is narrower: an institution that represents a decision as human-controlled should preserve evidence capable of testing whether the assigned authority had practical force.

1.4 Paper structure

Section 2 locates the procedure in meaningful-human-control, human-factors, oversight, incident-analysis, reconstruction, and assurance research. Section 3 defines the frozen method, artifact controls, literature search, and transfer boundary. Section 4 reports the released assessment and search results. Sections 5 through 7 separate interpretation, limitations, and proposed institutional record requirements.

2. Related work

2.1 Meaningful human control

Santoni de Sio and van den Hoven define meaningful human control through tracking and tracing. System behavior must respond to relevant human reasons, and human actors must be able to understand their role and bear responsibility (Santoni de Sio & van den Hoven, 2018). This account makes human presence insufficient because control depends on the relation among system behavior, human reasons, and identifiable responsibility. Later work moves the concept toward institutional and engineering use. Siebert et al. propose actionable properties that align ability, authority, and responsibility (Siebert et al., 2023). Davidovic argues that designers must first state the purpose served by human control (Davidovic, 2023). Calvert places proximal intervention inside a wider system of distal control across design, deployment, and governance (Calvert, 2025). Verdiesen, Santoni de Sio, and Dignum divide control across technical, sociotechnical, and governance layers (Verdiesen et al., 2021). Tsamados, Floridi, and Taddeo compare supervisory control with human-machine teaming for foundation-model systems (Tsamados et al., 2025). Zhu et al. frame oversight as human evaluative agency expressed through verification, steering, contestation, and substitution (Zhu et al., 2026). The present paper uses these sources to define the proposition being assessed. It does not offer a new philosophical account of meaningful human control.

2.2 Human oversight and the automation problem

Bainbridge shows how automation transfers rare, abnormal, and difficult work to people after routine operation has weakened the practice needed for that work (Bainbridge, 1983). Endsley connects autonomous-system performance to situation awareness, monitoring, workload, trust, and out-of-the-loop degradation (Endsley, 2017). Lee and See model appropriate reliance as a relation among the person, automation, task, and environment (Lee & See, 2004). Together, these mechanisms explain how nominal oversight can lose practical force. Human response to algorithmic advice is conditional. Alon-Barkat and Busuioc find both automation bias and selective adherence across experimental public-sector decisions (Alon-Barkat & Busuioc, 2023). Langer, Baum, and Schlicker separate the ability to detect error from a person's response tendency (Langer et al., 2024). Haselager et al. propose a counterargument prompt

that supports questioning of medical decision-support advice (Haselager et al., 2023). Dhanorkar, Passi, and Vorvoreanu identify a priori control, co-planning, real-time monitoring, and post hoc review in interviews with 17 experienced developers who use software agents (Dhanorkar et al., 2026). Two retained empirical sources expose di erent gaps between assigned oversight and practical e ect. In a secondary analysis of 99 Tesla-user interviews, Suryana et al. report that perceived safety sometimes coexisted with failures to track driver reasons; takeover readiness and prior reliable experience also shaped perception (Suryana et al., 2024). The study concerns reported perception in partial driving automation and does not observe incident-control outcomes. In a 28-participant sandbox study, Li et al. report task-completion rates of 83.3 percent under direct manipulation and 61.9 percent under text guidance; delayed responses and di cult error correction also made intervention e ects harder for participants to assess (Li et al., 2025). The sample, tasks, model, and single qualitative coder limit transfer. Together, the studies support a mechanism claim: perceived control and formal feedback access can remain separate from demonstrated intervention e ect. E ectiveness also depends on causal and institutional conditions. Sterz et al. identify causal power, epistemic access, self-control, and tting intentions (Sterz et al., 2024). Baum and Laux distinguish constitutive human participation from corrective oversight and require genuine preparedness and capacity for the latter (Baum & Laux, 2026). Te'eni, Yahav, and Schwartz treat continual human learning as a condition for stable and adaptive control (Te'eni et al., 2025). Laux proposes institutional safeguards that anticipate fallible competence and incentives (Laux, 2024). Green's policy analysis reaches a related implication: oversight rules need evidence that people can perform the assigned review (Green, 2022). The present method converts these constructs into documentary questions about information, comprehension, authority, feasibility, action, and e ect. Design and governance research also show why those conditions depend on system architecture. Van der Waa et al. use human-agent team patterns to make allocation timing, su cient understanding, halt or resume capability, and handover conditions explicit (van der Waa et al., 2020). Kolt argues that monitoring and detailed records can reduce information asymmetry and support intervention, while speed, opacity, and irreversible action can make conventional oversight ine ective (Kolt, 2025). The rst source o ers conceptual design patterns and the second o ers legal analysis. Neither supplies a eld estimate of e ective control.

2.3 AI incident analysis and missing records

The AI Incident Database was created to provide a shared record of real-world failures and support learning across incidents (McGregor, 2021). Its reports remain public-source records with changing coverage and varying detail. Pittaras and McGregor respond to that constraint through expert classi cation of goals, technologies, and possible technical failure causes (Pittaras & McGregor, 2023). Paeth et al. show that incident reports contain structural ambiguity and unavoidable epistemic uncertainty (Paeth et al., 2025). These limits support an explicit indeterminate state. Macrae demonstrates that public investigative reports can support systematic analysis of sociotechnical failure in an autonomous system (Macrae, 2022). Ezell, Roberts-Gaal, and Chan specify system, contextual, cognitive, access, tool, log, and documentation information needed to investigate AI-agent incidents (Ezell et al., 2025). Wei and Heim locate those information needs inside institutional reporting systems and post-reporting action (Wei & Heim, 2026). The present method applies a narrower question to each packet: which records support a claim that assigned human authority could a ect the bounded action?

2.4 Reconstruction, forensics, and assurance

Dekker treats accident reconstruction as recovery of what people could know and why their actions made sense inside the unfolding event (Dekker, 2002). This approach guards against hindsight and unsupported counterfactual blame. McDermid identi es time, knowledge independent of the automated system, and practiced skill as conditions for e ective intervention (McDermid, 2019). These works closely anticipate

the procedure's reconstruction logic and feasible-challenge stage. Reconstruction output also depends on the analytic frame and the available record. Zhang, Jing, and Sun assigned separate teams to apply HFACS, AcciMap, and STAMP to the same o cial report of the Tianjin Port re and explosion (Zhang et al., 2018). The methods produced di erent factor sets, and the authors state that missing report detail can hide material factors. One accident, analyst reconciliation, and dependence on one o cial report prevent treating the comparison as a validation against event truth. The study supports the narrower rule used here: method choice and source completeness must remain visible when a public-record reconstruction is interpreted. Argument-based assurance asks whether evidence justi es a stated claim under explicit assumptions and uncertainty. Burr and Leslie extend that structure to ethical and social claims (Burr & Leslie, 2023). AMLAS applies it to machine-learning safety across development and deployment (Paterson et al., 2025). Lam et al. de ne scope, criteria, evidence, and reporting for assurance audits of algorithmic systems (Lam et al., 2024). The present procedure borrows this claim-evidence discipline for retrospective assessment. It issues no safety case for Oko or Patriot. Recent forensic work provides closer technical neighbors. Leung et al. reconstruct changing AI system state for insurance claims (Leung et al., 2026). Ledjaki et al. preserve and replay prompt-level evidence through a chain-of-custody design (Ledjaki et al., 2026). These papers constrain the contribution to the speci c combination of practical human control, public case selection, categorical missingness, and executable repository checks. ScientistOne supplies a closer architecture for research veri ability. Its Chain-of-Evidence framework requires claims to trace to evidence, and its post-hoc audit checks scores, speci cation violations, references, and method-code alignment (Meng et al., 2026). Moghaddam's argument graphs treat each AI-assisted step as a claim that must pass evidence and reasoning constraints before entering an o cial record (Moghaddam, 2026). Alhalangy integrates prediction, explanation, selective review, and an audit trail into a synthetic institutional decision pathway (Alhalangy, 2026). Lee, Yoon, and Lee position oversight authority, record duties, and auditability in the pre-design governance decision (Lee et al., 2026). These sources establish prior work for traceability, evidence-linked argument, and prospective record design. The present adaptation applies ve evidence- tness dimensions and dependency closure to retrospective public-case claims. Independent review has yet to test those judgments.

2.5 Synthesis

Existing research supplies theories of control, evidence about oversight performance, causal-role tax-onomies, institutional-design principles, retrospective reconstruction methods, public incident-analysis procedures, reporting requirements, assurance logic, claim-evidence architecture, and forensic evidence controls. This paper studies one governance-speci c integration of those elements in a frozen public-case procedure. The contribution is methodological and bounded. It asks how a reader can inspect the path from candidate selection to source packet, provenance label, assessment state, gure, and manuscript claim. The current evidence shows that the procedure can generate that path for three selected packets. It does not show that another assessor would agree, that the categories are valid across domains, or that use of the procedure improves institutional decisions.

3. Method

3.1 Study design

This is a retrospective, purposefully selected, single-assessor methods study. The unit of analysis is one bounded machine-mediated decision or action sequence. The method assesses documentary support for a practical-control proposition within that boundary. It does not assess personal blame, legal liability, or moral character.

3.2 System inclusion and transfer boundary

The frozen protocol used a functional and historically neutral system boundary. A case quali ed when an identi able machine-based system generated an inference, classi cation, recommendation, communication, decision, or action that a ected a person, institution, digital setting, or physical setting. Oko concerns a rule-based early-warning inference. The Patriot cases concern automated detection, tracking, classi cation, and engagement support. These systems di er materially from present learned models and agents. Transfer therefore depends on shared mechanisms such as time compression, information dependence, intervention rights, and causal e ect.

3.3 Protocol freeze and evidence cuto

The public-case protocol and empty selection register reached main at commit 180ddda1d70f0ee3 6faaf8875e839bbc99cbbec2. The evidence cuto was 6 August 2026 at 23:59:59 UTC. The protocol xed the candidate collections, eighteen search terms, six eligibility conditions, exclusion rules, chronological screening order, three strata, rst-eligible rule, and missing-data treatment. Candidate screening began after the freeze commit.

3.4 Candidate collections and search

The candidate pool came from two public collections. The AI Incident Database snapshot contained 1,607 incidents and 7,452 linked reports; 828 incidents matched at least one frozen term. The OECD AI Incidents and Hazards Monitor interface exposed the rst 100 rows returned by the frozen query. The snapshot and export are preserved with SHA-256 hashes in the selection register. The combined search output contains 928 candidate records. The OECD interface reported about 3,635 matches and capped export at 100 visible rows. Date probes found no OECD result before 2020, while all selected cases predated 2020 and came from the AI Incident Database.

3.5 Eligibility, strata, and stopping

An eligible case required an identi able system output or action, a bounded sequence, two reports from di erent authors or organizations, one primary or o cial record, lawful citation and analysis, and compliance with the evidence cuto . The incomplete-evidence stratum allowed two independent secondary reports after a documented unsuccessful search for an o cial record. Benchmark demonstrations, unbounded performance reports, single-source events, private-evidence dependencies, rights con icts, duplicates, and post-cuto evidence were excluded. Candidates were deduplicated, sorted by event date and collection identi er, and screened until the rst eligible case lled each of three strata: pre-action intervention, incomplete or con icting evidence, and authority without practical force. Screening stopped after ve candidates. The strata anticipate the headline contrasts. The case set therefore demonstrates procedure execution under those conditions and supplies no independent discrimination test.

3.6 Versioned evidence packets

Each selected case packet de nes the action boundary and chronology; lists title, issuer, author, dates, URLs, source class, and preservation state; records unavailable evidence; labels material statements; states publication-rights limits; and preserves hashes for locally stored les. Remote-only sources are cited with metadata and retrieval information. The packet manifest proves the bytes preserved in the repository at that version. It makes no claim about later remote content or source truth.

Figure 1. Frozen selection and stopping. The gure shows the chronological decisions for the ve screened candidates and the point at which all three strata were lled.

3.7 Assessment contract

The assessment contract records six autonomy variables, twelve trust-evidence propositions, and nine practical-control stages. The current paper compares six pre-action stages: access, comprehension, authority, feasibility, exercise, and e ect. Every stage receives one categorical state: supported, partially supported, unsupported, indeterminate, or outside scope. Material statements receive one provenance label: direct record, source claim, assessor inference, or unresolved. A bounded practical-force conclusion requires supported ndings for access, authority, feasibility, exercise, and e ect. Correction and repair are required for a wider institutional-accountability conclusion. Reform requires longitudinal evidence.

Table 1. Assessment-state decision rules.

State	Code	Decision rule
Supported	S	Direct, contemporaneous evidence satis es the stage de nition.
Partially supported	P	Some required elements are present and a material gap remains.
Unsupported	U	Available evidence contradicts the stage or shows that the condition was absent.
Indeterminate	I	The packet lacks enough evidence to decide.
Outside scope	O	The stage does not apply within the declared case boundary, with a written reason.

Note. A missing record produces an indeterminate state unless the protocol or case design establishes that the record should exist. The states are categorical. No numeric distance or aggregate score is assigned.

3.8 Missing evidence and inference

Missing public evidence produces an indeterminate state unless the packet establishes that a required record should exist and eligible evidence shows the condition was absent. This rule blocks a common inference error in retrospective work: converting an unavailable log, display, inquiry, or internal record into a nding that the underlying condition failed. The report separates what a source states, what a preserved record directly shows, what the assessor infers, and what remains unresolved.

3.9 Artifact and consistency controls

Repository checks validate schemas, packet hashes, selection invariants, cross-case interactions, derived gure data, release manifests, and prespeci ed mutations. These checks reproduce declared transformations and detect internal contradictions. They do not reproduce the assessor's historical judgments. The v0.6 Chain-of-Evidence adaptation maps each material claim to exact locators, records a human support attestation, and tests directness, contemporaneity, independence, completeness, and publication authority. A dependency graph controls which claims may enter a conclusion. The integrity audit adapts ScientistOne's score veri cation, speci cation-violation, reference-veri cation, and method-code-alignment checks, then adds evidence- tness and dependency-closure checks. A separate literature-support register maps material manuscript sentences to checked references.

3.10 Formal literature search

A v0.7 protocol xed eight query families, inclusion rules, screening states, deduplication, fteen citation seeds, and a contribution rejection test before retrieval. Semantic Scholar served as the controlling reproducible index. Every direct-search token and every returned citation page were retrieved. Crossref checked DOI metadata, while OpenAlex compared seed coverage. Publisher, proceedings, preprint, and institutional pages were used to verify the close set. AI assistance assigned preliminary triage proposals. Mark Julius Banasihan reviewed the initial 89-record queue and remains accountable for every recorded decision. A separate frozen protocol governed AI-assisted screening of 71 recovered forward citations under his authorization. A v0.14 proposition protocol then required a stable locator, exact passage, bounded proposition, ve-dimension tness decision, limitation, reversal condition, and permission state for each of the 13 close sources. Five received bounded manuscript permission, two remain background-only, and six are quarantined. A direct-query overlay closed the fth screening decision while preserving zero source-content permission. An abstract-only record supports only a bounded description of the source's declared purpose or model. A wider substantive claim requires checked full text and a stable proposition locator. Authenticated Scopus or Web of Science access and several disciplinary interfaces remain open.

3.11 Frozen Oko adjudication

The v0.6 adjudication asked which states follow when the existing de nitions are applied to the frozen Oko packet. It admitted no new historical source. The evidence cuto , packet, six stage questions, state rules, and dependency rule were xed before reassessment. Retrospective rst-person testimony directly supports what a participant later reported. Its publication date prevents it from satisfying the contemporaneous-record requirement for a supported 1983 state. The v0.3.0 assessment remains preserved. A separate ledger records each v0.6 change.

4. Results

4.1 Selection result

The search preserved 928 candidate records. Five candidates were screened in chronological order. Two were excluded: one lacked two independent reports of a bounded autonomous action, and one lacked a bounded action sequence. AIID-27 lled pre-action intervention, AIID-444 lled authority without practical force, and AIID-445 lled incomplete or con icting evidence. Screening then stopped. The remaining 923 candidates carry no exclusion decision.

4.2 Oko, 1983

The v0.3.0 release classi ed access, comprehension, authority, feasibility, exercise, and e ect as supported. The frozen v0.6 adjudication classi es all six as partially supported. The packet contains retrospective participant accounts and an independent retrospective reconstruction. It contains no located contemporaneous Soviet command log, o cial incident record, or investigation le. The correction aligns the state labels with the evidence rule and preserves the missing historical record as a limitation. The packet supports a bounded account of what later sources report. It supplies no sole-cause nding for the ultimate outcome.

4.3 Patriot ZG710, 2003

The ZG710 packet supports formal engagement authority. It records a decision window of about one minute, incomplete communication, restricted access to the wider air picture, training that emphasized trust in the system, and identi cation weaknesses. Within the packet, comprehension, feasible challenge, exercised challenge, and protective e ect are unsupported. The assessment addresses the practical-control chain. It assigns no individual legal or moral responsibility.

4.4 Patriot F/A-18C, 2003

The F/A-18C packet supports the detection-to-engagement sequence and formal authority. The full inquiry, system logs, operator displays, and classi ed technical report were unavailable. Access is partially supported; comprehension, feasibility, and exercised challenge are indeterminate; e ect is unsupported because the engagement proceeded and the aircraft was lost. The unresolved states preserve the di erence between a missing public record and evidence that a condition failed.

4.5 Cross-case practical-control chain

Figure 2 compares the six pre-action stages. Oko carries partial support across the chain. ZG710 carries supported authority, partial access, and unsupported comprehension, feasibility, exercise, and e ect. F/A-18C carries supported authority, partial access, indeterminate comprehension, feasibility, and exercise, and unsupported e ect.

Table 2. Practical-control states across three public cases.

Stage	Oko, 1983	Patriot ZG710, 2003	Patriot F/A-18C, 2003
Access before action	P	P	P
Comprehension	P	U	I
Formal authority	P	S	S
Feasible challenge	P	U	I
Exercised challenge	P	U	I
Protective e ect	P	U	U
Correction	O	O	O
Repair	O	U	U
Institutional reform	P	S	S

Note. S = supported; P = partially supported; U = unsupported; I = indeterminate; O = outside scope. The table reports 27 item-level ndings. It supplies no frequency, causal, or population estimate.

Figure 2. Practical-control chain. The result shows that assigned authority can coexist with di erent states for information, understanding, opportunity, action, and e ect. The comparison reports the procedure's output for purposefully selected cases. It supplies no frequency estimate.
